F08NVF (CGEBAL/ZGEBAL) - NAG Fortran Library Routine Document

Note. Before using this routine, please read the Users' Note for your implementation to check the interpretation of bold italicised terms and other implementation-dependent details.

1 Purpose

F08NVF (CGEBAL/ZGEBAL) balances a complex general matrix in order to improve the accuracy of computed eigenvalues and/or eigenvectors.

2 Specification

SUBROUTINE FO8NVF(JOB, N, A, LDA, ILO, IHI, SCALE, INFO) ENTRY cgebal(JOB, N, A, LDA, ILO, IHI, SCALE, INFO) INTEGER N, LDA, ILO, IHI, INFO real SCALE(*)

complex A (LDA,*)
CHARACTER*1 JOB

The ENTRY statement enables the routine to be called by its LAPACK name.

3 Description

This routine balances a complex general matrix A. The term 'balancing' covers two steps, each of which involves a similarity transformation of A. The routine can perform either or both of these steps.

1. The routine first attempts to permute A to block upper triangular form by a similarity transformation:

$$PAP^{T} = A' = \begin{pmatrix} A'_{11} & A'_{12} & A'_{13} \\ 0 & A'_{22} & A'_{23} \\ 0 & 0 & A'_{33} \end{pmatrix}$$

where P is a permutation matrix, and A'_{11} and A'_{33} are upper triangular. Then the diagonal elements of A'_{11} and A'_{33} are eigenvalues of A. The rest of the eigenvalues of A are the eigenvalues of the central diagonal block A'_{22} , in rows and columns i_{lo} to i_{hi} . Subsequent operations to compute the eigenvalues of A (or its Schur factorization) need only be applied to these rows and columns; this can save a significant amount of work if $i_{lo} > 1$ and $i_{hi} < n$. If no suitable permutation exists (as is often the case), the routine sets $i_{lo} = 1$ and $i_{hi} = n$, and A'_{22} is the whole of A.

2. The routine applies a diagonal similarity transformation to A', to make the rows and columns of A'_{22} as close in norm as possible:

$$A'' = DA'D^{-1} = \begin{pmatrix} I & 0 & 0 \\ 0 & D_{22} & 0 \\ 0 & 0 & I \end{pmatrix} \begin{pmatrix} A'_{11} & A'_{12} & A'_{13} \\ 0 & A'_{22} & A'_{23} \\ 0 & 0 & A'_{33} \end{pmatrix} \begin{pmatrix} I & 0 & 0 \\ 0 & D_{22}^{-1} & 0 \\ 0 & 0 & I \end{pmatrix}.$$

This scaling can reduce the norm of the matrix (that is, $||A''_{22}|| < ||A'_{22}||$), and hence reduce the effect of rounding errors on the accuracy of computed eigenvalues and eigenvectors.

5 Parameters

1: JOB — CHARACTER*1

Input

On entry: indicates whether A is to be permuted to and/or scaled (or neither), as follows:

if JOB = 'N', then A is neither permuted nor scaled (but values are assigned to ILO, IHI and SCALE);

if JOB = 'P', then A is permuted but not scaled;

if JOB = 'S', then A is scaled but not permuted;

if JOB = 'B', then A is both permuted and scaled.

Constraint: JOB = 'N', 'P', 'S' or 'B'.

2: N — INTEGER

Input

On entry: n, the order of the matrix A.

Constraint: $N \geq 0$.

3: A(LDA,*) — complex array

Input/Output

Note: the second dimension of the array A must be at least max(1,N).

On entry: the n by n general matrix A.

On exit: A is overwritten by the balanced matrix.

A is not referenced if JOB = 'N'.

4: LDA — INTEGER

Input

On entry: the first dimension of the array A as declared in the (sub)program from which F08NVF (CGEBAL/ZGEBAL) is called.

Constraint: LDA $\geq \max(1,N)$.

5: ILO — INTEGER

Output

6: IHI — INTEGER

Output

On exit: the values i_{lo} and i_{hi} such that on exit A(i,j) is zero if i > j and $1 \le j < i_{lo}$ or $i_{hi} < i \le n$.

If JOB = 'N' or 'S', then $i_{lo} = 1$ and $i_{hi} = n$.

7: SCALE(*) — real array

Output

Note: the dimension of the array SCALE must be at least max(1,N).

On exit: details of the permutations and scaling factors applied to A. More precisely, if p_j is the index of the row and column interchanged with row and column j and d_j is the scaling factor used to balance row and column j, then

$$\label{eq:SCALE} \begin{split} \text{SCALE}(j) = \left\{ \begin{aligned} p_j, & \text{for} j = 1, 2, \dots, i_{lo} - 1 \\ d_j, & \text{for} j = i_{lo}, i_{lo} + 1, \dots, i_{hi} \text{ and} \\ p_j, & \text{for} j = i_{hi} + 1, i_{hi} + 2, \dots, n. \end{aligned} \right. \end{split}$$

The order in which the interchanges are made is n to $i_{hi} + 1$, then 1 to $i_{lo} - 1$.

8: INFO — INTEGER

Output

On exit: INFO = 0 unless the routine detects an error (see Section 6).

6 Error Indicators and Warnings

INFO < 0

If INFO = -i, the *i*th parameter had an illegal value. An explanatory message is output, and execution of the program is terminated.

7 Accuracy

The errors are negligible, compared with those in subsequent computations.

8 Further Comments

If the matrix A is balanced by this routine, then any eigenvectors computed subsequently are eigenvectors of the matrix A'' (see Section 3) and hence F08NWF (CGEBAK/ZGEBAK) **must** then be called to transform them back to eigenvectors of A.

If the Schur vectors of A are required, then this routine must **not** be called with JOB = 'S' or 'B', because then the balancing transformation is not unitary. If this routine is called with JOB = 'P', then any Schur vectors computed subsequently are Schur vectors of the matrix A'', and F08NWF **must** be called (with SIDE = 'R') to transform them back to Schur vectors of A.

The total number of real floating-point operations is approximately proportional to n^2 .

The real analogue of this routine is F08NHF (SGEBAL/DGEBAL).

9 Example

To compute all the eigenvalues and right eigenvectors of the matrix A, where

$$A = \begin{pmatrix} 1.50 - 2.75i & 0.00 + 0.00i & 0.00 + 0.00i & 0.00 + 0.00i \\ -8.06 - 1.24i & -2.50 - 0.50i & 0.00 + 0.00i & -0.75 + 0.50i \\ -2.09 + 7.56i & 1.39 + 3.97i & -1.25 + 0.75i & -4.82 - 5.67i \\ 6.18 + 9.79i & -0.92 - 0.62i & 0.00 + 0.00i & -2.50 - 0.50i \end{pmatrix}.$$

The program first calls F08NVF (CGEBAL/ZGEBAL) to balance the matrix; it then computes the Schur factorization of the balanced matrix, by reduction to Hessenberg form and the QR algorithm. Then it calls F08QXF (CTREVC/ZTREVC) to compute the right eigenvectors of the balanced matrix, and finally calls F08NWF (CGEBAK/ZGEBAK) to transform the eigenvectors back to eigenvectors of the original matrix A.

9.1 Program Text

Note. The listing of the example program presented below uses bold italicised terms to denote precision-dependent details. Please read the Users' Note for your implementation to check the interpretation of these terms. As explained in the Essential Introduction to this manual, the results produced may not be identical for all implementations.
